MedMerge — *one safe list.*

DSH Hacks V2 · AI × Healthcare · Demo: shahriarsharif406.github.io/medmerge · Code: github.com/shahriarsharif406/medmerge

THE PROBLEM

In Bangladesh one medicine is sold under dozens of brand names — Napa and Ace are both paracetamol, Seclo and Losectil both omeprazole. Patients who see several doctors collect several prescriptions, and a double dose can hide behind two different names. Nobody reads them side by side.

WHAT MEDMERGE DOES

- Reads prescriptions (typed, or a photo via Gemini)
- Turns every brand into its active ingredient (12,000+ Bangladeshi brands)
- Merges them into one list and flags: same medicine under two names, hidden overlap inside combinations, same-family pairs, label-listed interactions
- Writes the questions to ask the doctor — in English and Bangla

WHY IT IS DIFFERENT

Existing tools check interactions in US/EU hospital records. MedMerge targets the Bangladeshi brand maze, works from a patient's phone, and runs entirely in the browser — no server, no stored data.

Built to be safe: it never says "stop"; it says "ask". Every scanned line is shown for confirmation. Not medical advice; interaction text is quoted from label summaries and not clinically validated.

HOW IT IS BUILT

Pure JavaScript engine (parser → brand/generic resolver with fuzzy matching → ingredient, class and label-text comparison), unit-tested in Node. Data: wsayan/medicinedb (MIT). Optional Gemini 2.5 Flash vision for photos using the user's own key. GitHub Pages hosting.
